SUMMARY

The thermo-hydro-mechanical (THM) coupling effects on the dynamic wave propagation and strain localization in a fully saturated softening porous medium are analyzed. The characteristic polynomial corresponding to the governing equations of the THM system is derived, and the stability analysis is conducted to determine the necessary conditions for stability in both non-isothermal and adiabatic cases. The result from the dispersion analysis based on the Abel–Ruffini theorem reveals that the roots of the characteristic polynomial for the THM problem cannot be expressed algebraically. Meanwhile, the dispersion analysis on the adiabatic case leads to a new analytical expression of the internal length scale. Our limit analysis on the phase velocity for the non-isothermal case indicates that the internal length scale for the non-isothermal THM system may vanish at the short wavelength limit. This result leads to the conclusion that the rate-dependence introduced by multiphysical coupling may not regularize the THM governing equations when softening occurs. Numerical experiments are used to verify the results from the stability and dispersion analyses.

1. INTRODUCTION

Localization of deformation in solids occurs in many natural processes and engineering applications. Examples of localization of deformation include the formation of Lüder and Portevin-Le Chatelier bands [1, 2] in metals and alloys, crack bands in concrete [3], and shear, compaction, and dilation bands in sand, clay, ice, and rocks [4–9]. For single-phase porous media under the static condition, the onset of strain localization is related to the loss of ellipticity, while the dynamics counterpart is due to the wave speed becoming imaginary [10–13]. These cases have been studied via stability and perturbation analyses in Hill [11, 14], which prove that perturbation grows instead of decays in unstable materials because of the ill-posedness of the governing equation. This ill-posedness of the governing equation, which can be triggered by strain softening and/or lack of normality [5], can lead to tremendous difficulty to replicate strain localization in computer simulations. One undesirable consequence is that the numerically simulated localization zones exhibit pathological dependence on the mesh size [12, 15–20]. As a result of this inherent mesh dependency, the size of mesh may affect the simulated post-bifurcation local and global responses, which do not converge upon mesh refinement [21, 22].

To circumvent this mesh dependency, a material length scale must be introduced in the governing equation. Belytschko et al. [23] summarized a number of ways to introduce length scale and coined them localization limiters. These methods include introducing non-local or gradient based
internal variables (e.g., [1, 24]), or higher-order continuum (e.g., [25–27]), and incorporating rate dependence in constitutive model (e.g., [12, 28]) to regularize the simulated responses after the onset of strain localization. This rate-dependent localization limiter is relevant to many deformation-diffusion coupling processes in multiphase materials, as the transient diffusion process is likely to introduce rate dependence to the mechanical responses due to the coupling effect. The previous works, such as Schrefler et al. [29, 30], Zhang and Schrefler [27], and Zhang et al. [31], analyze the rate-dependent effect in fluid-infiltrating porous solid via stability and dispersion analyses and derive the inherent length scale as a function of permeability and viscosity of the fluid among other material parameters. Benallal and Comi [32], Zhang and Schrefler [27], and Abellan and de Borst [33] argue that while dispersive effects are indeed observed in two-phase porous media, the physical length scale introduced via hydro-mechanical coupling effect vanishes at the short wavelength limit.

Nevertheless, the aforementioned stability and dispersion analyses are based on the assumptions that the porous media is under the isothermal condition and the thermal effect is negligible and decoupled from the hydro-mechanical processes. These assumptions are reasonable for numerous engineering applications in which thermal effect plays little role on the safety or efficiency of the operations. However, THM (thermo-hydro-mechanical) coupling effect is critical for various applications, such as geothermal energy piles [34], geological disposal of carbon dioxide and nuclear wastes [35], freezing-thawing of pavement systems [36], and landslide triggered by thermal induced creeping [37].

To the best knowledge of the authors, there is no study concerning the THM coupling effect on the inherent length scale of porous media under non-isothermal condition. The purpose of this article is to fill this important knowledge gap. In particular, we apply the Routh–Hurwitz stability theorem to the THM governing equations and determine whether small perturbation can grow into localized instability and whether dispersive wave can propagate at finite wave speed in a thermal-sensitive softening porous media under the general non-isothermal condition and the adiabatic limit. Our analysis indicates that the characteristic polynomial for the porous media under the general non-isothermal condition is of the fourth-order in the stability analysis, and of the sixth-order in the dispersion analysis. According to the Abel–Ruffini theorem (Abel’s impossibility theorem), a polynomial higher than the fifth-order has no general algebraic solution. As a result, we prove that it is impossible to express the internal length scale algebraically for the general non-isothermal case. On the other hand, under the adiabatic condition, we prove that the characteristic polynomial is reduced to the third-order for the dispersion analysis. Therefore, we derive the algebraic expression of length scale for this limit case and compare both new results with the previous works on isothermal porous media [29, 33, 38].

The rest of the paper is organized as follows. We first perform the stability analysis for both general non-isothermal and adiabatic cases, and determine the onset of instability in Section 2.2. We then investigate the dispersive wave propagation in Section 2.3. In particular, we derive the phase velocity for the non-isothermal case at the long wavelength limit, and the vanishing of the physical internal length scale is observed at the short wavelength limit. For many THM coupling processes at very small time scale, the thermal conductivity of the porous media is negligible. For those adiabatic cases, we derive the simplified expression of the internal length scales and analyze the wave propagation speed during strain softening. In Section 3, we conduct numerical experiments using an 1D dynamic THM finite element code to compare and validate the analytical derivation in Sections 2.2 and 2.3. Furthermore, the influences of hydraulic properties (permeability) and thermal parameters (thermal conductivity and specific heat) on internal length scale and wave propagation behavior are evaluated for both non-isothermal and adiabatic cases, respectively. Finally, concluding remarks are given in Section 4.

As for notations and symbols, bold-faced letters denote tensors; the symbol ‘:’ denotes a single contraction of adjacent indices of two tensors (e.g., \( a \cdot b = a_{ij}b_{ij} \) or \( c \cdot d = c_{ij}d_{jk} \)); the symbol ‘\( \cdot \)’ denotes a double contraction of adjacent indices of tensor of rank two or higher (e.g., \( e^{\epsilon} = C_{ijkl}e_{kl} \)); the symbol ‘\( \otimes \)’ denotes a juxtaposition of two vectors (e.g., \( \alpha \otimes \beta = a_{ij}\beta_{ij} \)) or two symmetric second order tensors (e.g., \( \alpha \otimes \beta = a_{ij}\beta_{ij} \)). As for sign conventions, we consider the direction of the tensile stress and dilatative pressure as positive.
2. STABILITY AND DISPERSION ANALYSES

In this section, the governing equations for the wave propagation of a one-dimensional softening bar composed of fully saturated porous media under the general non-isothermal and adiabatic conditions are introduced. We perform stability and dispersion analyses on both cases and obtain the corresponding characteristic polynomials. Then, we derive the explicit expression of phase velocity and determine the vanishing length scale under long and short wavelength limits for the non-isothermal condition. In the adiabatic condition, analytical derivations of the cutoff wavenumber and internal length scale are investigated for dynamic wave propagation in a two-phase porous medium. These new results are compared with the stability and dispersion analyses for isothermal porous media.

2.1. Model assumptions and governing equations

The THM response of fluid infiltrating porous solids is governed by the balance principles, that is, the balance of linear momentum, mass, and energy. Biot [39] formulated a general thermodynamics theory for non-isothermal porous media. McTigue [40] derived a field theory for the linear thermo-elastic response of fully saturated porous media. This model is extended in Coussy [41] to incorporate the structural heating effect. Belotserkovets and Prêvost [42] derived analytical solutions of an elastic fluid-saturated porous sphere subjected to boundary heating, prescribed pore pressure, and flux. Selvadurai and Suvorov [43] analyzed the same THM problem of a spherical domain. By neglecting the heat generated and dissipated due to deformation of the solid skeleton and the flow convection of the porous spheres, the analytical solution of THM responses of the sphere composed of a fluid-saturated elasto-plastic material was derived and compared with finite element solution.

In this study, we adopt the governing equations of Coussy [41] and Belotserkovets and Prêvost [42]. We assume that the strain is infinitesimal and that there is no mass exchange between the solid and fluid constituents. The gravitational body force and heat convection of among the constituents are neglected. Furthermore, we ignored the difference between the acceleration of the fluid and solid skeleton in Eq. (1) and Eq. (2) to simplify the analysis as previously carried out in Zhang et al. [29], Zienkiewicz et al. [44]. As a result, the governing equations of the linear momentum, the fluid mass balance, and the energy balance read,

\[ \nabla \cdot (\sigma' - \beta p - \beta T) - \rho \ddot{u} = 0, \]  
(1)

\[ b \nabla \cdot \dot{u} - k \nabla^2 p + \frac{1}{M} \ddot{p} - 3n \alpha_m \dot{T} = 0, \]  
(2)

\[ \rho c_p \dot{T} - k \nabla^2 T + T_0 \beta \nabla \cdot \dot{u} - 3n \alpha_m T_0 \ddot{p} = 0, \]  
(3)

where \( \sigma' \) is effective stress (nominal effective stress in Liu et al. [45]), \( p \) is pore pressure, \( T \) is temperature, \( u \) is displacement of solid skeleton, and \( b \) is the Biot’s coefficient. The mobility, \( k \), is defined as \( k = k_s / \mu_f = k_{perm} / \rho_f g \), in which \( k_s \) is the intrinsic permeability, \( \mu_f \) is the fluid viscosity, \( k_{perm} \) is the permeability or hydraulic conductivity, and \( g \) is the gravity acceleration. Furthermore, \( T_0 \) is the reference temperature as defined in [42]. \( \beta \) is calculated as \( \beta = 3 \alpha_s K \), in which \( \alpha_s \) is the linear thermal expansion coefficient of solid, and \( K \) is the bulk modulus. Also, the volume averaged thermal expansion coefficient \( \alpha_m \) is expressed as \( \alpha_m = (b - n) \alpha_s + n \alpha_f \), a function of porosity \( n \) and the linear thermal expansion coefficient of fluid \( \alpha_f \). Here, \( \rho \) = \((1 - n)\rho_s + np_f\), in which \( \rho_s \) and \( \rho_f \) are solid and fluid mass densities, \( k \) is the thermal conductivity, and \( c_s, c_f \) are the specific heat per unit mass of solid and fluid. The Biot’s modulus is denoted as \( M \), which is a function of the Biot’s coefficient \( b \), porosity \( n \), the bulk modulus of the solid grain \( K_s \), and that of the fluid constituent \( K_f \), that is,

\[ \frac{1}{M} = \frac{b - n}{K_s} + \frac{n}{K_f}. \]  
(4)

In this study, the volume-averaged specific heat of the constituents, \( \rho c = (1 - n)\rho_s c_s + np_f c_f \), is considered to be specific heat of two-phase fluid-solid mixture. In addition, we assume that the
temperature is at equilibrium locally and hence there is no temperature difference between the two constituents at the same material point. To simplify the stability and dispersion analyses, we limit our attention to a one-dimensional dynamic THM boundary value problem.

2.2. Stability analysis

In this section, we analyze stability of a one-dimensional wave propagation in a thermal-sensitive fluid-saturated porous media. Our goal here is to determine the necessary and sufficient conditions to maintain stability of the THM system in the generalized non-isothermal case and at the adiabatic limit. Our results are compared with the previous analyses on isothermal porous media. In particular, we apply the Routh–Hurwitz stability theorem to the characteristic equations of the general non-isothermal and adiabatic THM systems. The Routh–Hurwitz criterion enables us to determine whether it is possible that the solution of characteristic equation can have a real and positive part, which in return implies that homogeneous state is unstable and a small perturbation may grow [1].

2.2.1. Non-isothermal case. To investigate the stability of an equilibrium state, we apply a harmonic perturbation with respect to an incremental axial displacement, pore pressure, and temperature. For an infinite one-dimensional thermo-sensitive porous medium initially in a homogeneous state, the solution of displacement, pore pressure, and temperature in space-time \( x; t \) may take the following form,

\[
\begin{bmatrix}
\frac{du}{dt} \\
\frac{dp}{dt} \\
\frac{dT}{dt}
\end{bmatrix} = \begin{bmatrix}
A_u \\
A_p \\
A_T
\end{bmatrix} e^{i(k_w x - \omega t)} = A e^{i k_w x + \lambda t}, \quad \lambda = -i \omega, \quad (5)
\]

where \( k_w \) is the wavenumber, \( \omega \) the angular frequency, and \( \lambda \) eigenvalue. \( A_u, A_p, \) and \( A_T \) are the amplitudes of the displacement, pore pressure, and temperature perturbations, respectively. Following the approach in Zhang et al. [29] and Abellan and de Borst [33], we use an incremental linear constitutive model to relate the infinitesimal change of the nominal effective stress and that of the total strain for the one-dimensional THM problem, that is,

\[
\dot{\sigma}' = E_t \frac{\partial \dot{u}}{\partial x} = E_t \dot{\varepsilon}, \quad (6)
\]

where \( E_t \) is the tangential stiffness modulus of the solid (cf. Abellan and de Borst [33]). The relations among the one-dimensional total stress \( \sigma \), Biot’s effective stress \( \sigma'' \), and the nominal effective stress \( \sigma' \) are [45],

\[
\dot{\sigma} = \dot{\sigma}'' - b \dot{p} = \dot{\sigma}' - \dot{\beta} \dot{T} - b \dot{p}. \quad (7)
\]

The spatial derivative of the incremental nominal effective stress Eq. (6) gives

\[
\frac{\partial \dot{\sigma}'}{\partial x} = -E_t A_u k_w^2 \exp(i k_w x + \lambda t). \quad (8)
\]

The substitution of Eq. (5) into Eqs. (1) to (3) therefore gives

\[
\begin{align*}
-E_t k_w^2 A_u - i (b k_w) A_p - i (\beta k_w) A_T - \rho \lambda^2 A_u &= 0, \\
i (bk_w \lambda) A_u + k k_w^2 A_p + M^{-1} \lambda A_p - 3 \alpha_m \lambda A_T &= 0, \\
\rho c \lambda A_T + k k_w^2 A_T + i (T_0 \beta k_w \lambda) A_u - 3 \alpha_m T_0 \lambda A_p &= 0.
\end{align*} \quad (9) \quad (10) \quad (11)
\]

A non-trivial solution to this set of homogeneous equations exists if and only if the following relation holds

\[
\begin{vmatrix}
-E_t k_w^2 - \rho \lambda^2 & -i (b k_w) & -i (\beta k_w) \\
-i (bk_w \lambda) & k k_w^2 + M^{-1} \lambda & -3 \alpha_m \lambda \\
i (T_0 \beta k_w \lambda) & -3 \alpha_m T_0 \lambda & \rho c \lambda + k k_w^2 \\
\end{vmatrix} = 0. \quad (12)
\]
which can be rewritten as shown in the succeeding equation,

\[ (-E_1k_w^2 - \rho \lambda^2) \left[ (kk_w^2 + M^{-1} \lambda) (\rho c \lambda + \kappa k_w^2) - (-3\alpha_m \lambda) (-3\alpha_m T_0 \lambda) \right] \\
+ i(bk_w) \left[ i(bk_w) (\rho c \lambda + \kappa k_w^2) - (-3\alpha_m \lambda) (i (T_0 \beta k_w \lambda)) \right] \\
- i(\beta k_w) \left[ i(bk_w) (-3\alpha_m T_0 \lambda) - (kk_w^2 + M^{-1} \lambda) (i (T_0 \beta k_w \lambda)) \right] = 0. \tag{13} \]

Expanding Eq. (13) yields

\[ -\frac{1}{M} \rho^2 c \lambda^4 + 9\alpha_m^2 \rho b T_0 \lambda^4 - \frac{1}{M} \rho \kappa k_w^2 \lambda^3 - \rho^2 c k k_w^2 \lambda^3 - \frac{1}{M} \rho c E_1 k_w^2 \lambda^2 - \rho c b_k^2 k_w^2 \lambda^2 \\
- \rho \kappa k_w^4 \lambda^2 - \frac{1}{M} \beta^2 T_0 k_w^2 \lambda^2 - 6\alpha_m \beta b T_0 k_w^2 \lambda^2 + 9E_1 \alpha_m^2 T_0 k_w^2 \lambda^2 \\
- \frac{1}{M} E_1 k_w^4 \lambda - b^2 k_w^4 \lambda - \rho c E_1 k k_w^4 \lambda - \beta^2 k T_0 k_w^4 \lambda - E_1 k k M k_w^6 = 0, \tag{14} \]

in which the terms in Eq. (14) are rearranged in descending order for eigenvalue, \( \lambda \). Simplifying the expression of Eq. (14) yields \( M \neq 0 \),

\[ \rho (\rho c - 9\alpha_m^2 T_0 M) \lambda^4 + \rho (\kappa + \rho c k M) k_w^2 \lambda^3 + (\rho c E_1 + \rho c b^2 M + \rho \kappa M k_w^2) \\
+ \beta^2 T_0 + 6\alpha_m \beta b T_0 M - 9E_1 \alpha_m^2 T_0 M) k_w^2 \lambda^2 \\
+ (E_1 \kappa + b^2 k M + \rho c E_1 k M + \beta^2 k T_0 M) k_w^4 \lambda + E_1 k \kappa M k_w^6 = 0. \tag{15} \]

After rearranging Eq. (15), the characteristic equation is a forth-order polynomial that reads,

\[ a_4 \lambda^4 + a_3 \lambda^3 + a_2 \lambda^2 + a_1 \lambda + a_0 = 0. \tag{16} \]

with the following real coefficients,

\[ a_4 = \rho (\rho c - 9\alpha_m^2 T_0 M), \tag{17} \]
\[ a_3 = \rho (\kappa + \rho c k M), \tag{18} \]
\[ a_2 = (\rho c E_1 + \rho c b^2 M + \rho \kappa M k_w^2 + \beta^2 T_0 + 6\alpha_m \beta b T_0 M - 9E_1 \alpha_m^2 T_0 M) k_w^2, \tag{19} \]
\[ a_1 = (E_1 \kappa + b^2 k M + \rho c E_1 k M + \beta^2 k T_0 M) k_w^4, \tag{20} \]
\[ a_0 = E_1 k \kappa M k_w^6. \tag{21} \]

According to the Routh–Hurwitz stability criterion, the stability of the governing equations is maintained if and only if all the solutions of characteristic polynomial have negative real part [46, 47]. For the fourth-order polynomial shown in Eq. (16), the necessary condition to satisfy the Routh–Hurwitz stability criterion is to have the coefficients listed in Eqs. (17) to (21) hold the following properties,

\[ a_n > 0, \ a_3 a_2 > a_4 a_1, \ \text{and} \ a_3 a_2 a_1 > a_4 a_1^2 + a_3^2 a_0, \ \text{where} \ n = 0, 1, 2, 3, 4. \tag{22} \]

We first examine Eq. (22), which requires all coefficients \( a_i, i = 0, 1, 2, 3, 4 \), to be strictly positive. Notice that these coefficients are all functions of the material parameters that characterize the mechanical, hydraulic, and thermal responses of porous media. As a result, one may deduce the necessary condition to satisfy Eq. (22) by examining the physical meaning and the possible ranges of the material parameters. Here, we categorize the material parameters into three groups – strictly positive, non-negative, and real number (which can be negative, zero, or positive). Among these three groups, we first assume that the total density \( \rho \), specific heat \( c \), Biot’s modulus \( M \), and Biot’s coefficient \( b \) are all strictly positive and hence greater than zero. Meanwhile, the mobility \( k \), thermal conductivity \( \kappa \), thermal expansion coefficient \( \alpha_m \), and the reference temperature \( T_0 \) are assumed to
Furthermore, a necessary and sufficient condition for material softening is not the only indicator that detects the loss of stability in the THM problem. Porous medium is vulnerable to significant thermal expansion (e.g., marine clay). This indicates that equations to lose stability if the fluid and solid constituents are both nearly incompressible but the

be non-negative (if the temperature unit is Kelvin). Finally, the tangential stiffness $E_t$ can be both positive, negative, or zero, as summarized in Table I.

With the aforementioned assumptions in mind, we notice that $a_0, a_1,$ and $a_3$ may all become non-positive when both thermal conductivity and permeability of the material become zero. This result indicates that the wave propagating in non-isothermal porous medium may lose stability at the undrained limit even though there is no softening. At the adiabatic limit, we found that one of the roots of the characteristic polynomial is zero and at least one of the root may have a positive real part if at least one of the four conditions listed at the end of Section 2.2.2 is met. On the other hand, $a_4$ is greater than zero if both solid and fluid constituents do not exhibit thermal expansion such that $\alpha_m = 0$. However, to maintain stability, the specific heat must be large enough such that $c > 9\alpha_m^2 T_0 M / \rho$. In other words, from a theoretical standpoint, it is possible for the THM governing equations to lose stability if the fluid and solid constituents are both nearly incompressible but the porous medium is vulnerable to significant thermal expansion (e.g., marine clay). This indicates that material softening is not the only indicator that detects the loss of stability in the THM problem. Furthermore, a necessary and sufficient condition for $a_0 > 0, a_1 > 0,$ and $a_2 > 0$ is to have $E_t > 0$, that is, no softening occurring. A few algebraic operations reveal that,

$$a_2 > 0 \text{ implies that } E_t = \frac{-\rho c h^2 M - \rho c k M k_w^2 + \beta^2 T_0 - 6 \alpha_m \beta b T_0 M}{\rho c - 9 \alpha_m^2 T_0 M} > 0,$$  

(23)

$$a_1 > 0 \text{ implies that } E_t = \frac{-b^2 M - \beta^2 k T_0 M}{\kappa + \rho c k M} > 0.$$  

(24)

Because the stability condition also requires $a_4 > 0$ and hence $\rho c - 9 \alpha_m^2 T_0 M > 0$, both (23) and (24) would not be violated unless softening occurs (i.e., $E_t < 0$). Meanwhile, the explicit expression of $a_3 a_2 > a_4 a_1$ reads,

$$k \kappa^2 M \rho^2 k_w^6 + b^2 c^2 k M^2 \rho^3 k_w^6 + c k^2 M^2 \rho^3 k_w^2 + \beta^2 k \rho T_0 k_w^4 + 6 \alpha_m \beta b \kappa M \rho T_0 k_w^4 + 9 \alpha_m^2 b^2 k M^2 \rho T_0 k_w^4 > 0,$$  

(25)

which can be expressed as in the succeeding equation,

$$\rho k_w^4 \left[ \beta^2 c k M^2 k_w^2 + \kappa T_0 (\beta + 3 \beta \alpha_m M)^2 + k M \left( \rho c k_w^2 + M (b \rho c + 3 \beta \alpha_m T_0)^2 \right) \right] > 0.$$  

(26)

Condition (26) always holds if the wavenumber is real, either the permeability or the thermal conductivity is non-zero and the rest of the material parameters are strictly positive. Finally, $a_3 a_2 a_1 > a_4 a_1^2 + a_2^2 a_0$ can be expanded as,

(27)

which can be further simplified as

\[
E_i \rho k_w^8 (\kappa + \rho c k M) \left[ 6 \alpha_m b \beta M T_0 (\kappa + \rho c k M) + b^2 M^2 (\rho^2 c^2 k + 9 \alpha_m^2 k T_0) + \beta T_0 (\kappa + 9 \alpha_m^2 k M^2 T_0) \right] + \rho k_w^8 M \left[ b^2 k_M^3 T_0 + \kappa T_0 (\beta + 3 \alpha_m b M)^2 + k M (\kappa^2 + M (\rho c + 3 \alpha_m \beta T_0)^2) \right] > 0.
\]

(28)

In other words, \( a_3 \alpha_3 \alpha_3 > a_4 a_1^2 + a_2 a_0 \) implies that

\[
E_i > -M(\kappa^2 + \beta T_0) (\rho^2 c^2 k M^2 k_w^2 + \kappa T_0 (\beta + 3 \alpha_m b M)^2 + k M (\kappa^2 + M (\rho c + 3 \alpha_m \beta T_0)^2)) = 0.
\]

(29)

which would not be violated unless softening occurs (i.e., \( E_i < 0 \)) as the aforementioned Eqs. (23) and (24).

As a result, the THM governing equations may fail the Routh–Hurwitz criterion if at least one of the following situations happens:

1. Softening occurs such that \( E_i < 0 \).
2. Both permeability and thermal conductivity of the porous media become zero.
3. Specific heat \( c \leq 9 \alpha_m^2 T_0 M / \rho \).

2.2.2. Adiabatic case. The stability analysis conducted in the previous section can be significantly simplified by assuming that the entire one-dimensional bar is in the adiabatic or isothermal condition. While the latter case has been extensively studied in the past (cf. Abellan and de Borst [29], Zhang and Schrefler [27, 38], Zhang et al. [33]), the stability analysis of adiabatic porous media has not yet been established. For many engineering applications in which high-rate and shock responses are of interest, it is reasonable to assume that the thermal conductivity is negligible. In those cases, we may derive the characteristic equation for the adiabatic condition by assuming the thermal conductivity to be zero, \( \kappa \approx 0 \). As a result, the characteristic equation of the adiabatic THM system reads,

\[
\begin{vmatrix}
-E_i k_w^2 - \rho \lambda^2 & -i (b k_w) & -i (\beta k_w) \\
-i (b k_w) & k k_w^2 + M^{-1} \lambda & -3 \alpha_m \lambda \\
i (T_0 \beta k_w) & -3 \alpha_m T_0 \lambda & -\rho c \lambda
\end{vmatrix} = 0.
\]

(30)

which can be rewritten as shown in the next equation,

\[
\begin{align*}
(-E_i k_w^2 - \rho \lambda^2) \left[ (k k_w^2 + M^{-1} \lambda) \rho c \lambda - (-3 \alpha_m \lambda) (-3 \alpha_m T_0 \lambda) \right] + i (b k_w) \left[ i (b k_w) \rho c \lambda - (-3 \alpha_m \lambda) (i (T_0 \beta k_w)) \right] \\
- i (\beta k_w) \left[ i (b k_w) (-3 \alpha_m T_0) - (k k_w^2 + M^{-1} \lambda) (i (T_0 \beta k_w)) \right] &= 0.
\end{align*}
\]

(31)
Expanding Eq. (31) yields

\[
- \frac{1}{M} \rho^2 c^4 + 9\rho\alpha_m^2 T_0 \lambda^4 - \rho^2 c k w^2 \lambda^3 - \frac{1}{M} \rho c E_t k w^2 \lambda^2 - \frac{3}{2} \rho b^2 k w^2 \lambda^2 \\
- \frac{1}{M} \beta^2 T_0 k_w^2 \lambda^2 - 6\alpha_m \beta b T_0 k_w^2 \lambda^2 + 9 E_t \alpha_m^2 T_0 k_w^2 \lambda^2 \\
- \rho c E_t k w^2 \lambda - \beta^2 T_0 k w^4 \lambda = 0,
\]

which can be rewritten as

\[
- \frac{1}{M} \lambda \left[ \rho \left( \rho c - 9\alpha_m^2 T_0 M \right) \lambda^3 + \rho^2 c k M k_w^2 \lambda^2 + \left( \rho c E_t + \rho c b^2 M + \beta^2 T_0 + 6\alpha_m \beta b T_0 M \right) \lambda \right] - 9 E_t \alpha_m^2 T_0 M k_w^2 \lambda + \left( \rho c E_t + \beta^2 T_0 \right) k M k_w^4 \lambda = 0.
\]

This equation can be expressed into a more compacted form that reads \( M \neq 0 \),

\[
b_3 \lambda^4 + b_2 \lambda^3 + b_1 \lambda^2 + b_0 \lambda = 0 \text{ or } (b_3 \lambda^3 + b_2 \lambda^2 + b_1 \lambda + b_0) \lambda = 0,
\]

where the expressions of the coefficients are

\[
b_3 = \rho \left( \rho c - 9\alpha_m^2 T_0 M \right),
\]

\[
b_2 = \rho^2 c k M k_w^2,
\]

\[
b_1 = \left( \rho c E_t + \rho c b^2 M + \beta^2 T_0 + 6\alpha_m \beta b T_0 M - 9 E_t \alpha_m^2 T_0 M \right) k_w^2.
\]

\[
b_0 = \left( \rho c E_t + \beta^2 T_0 \right) k M k_w^4.
\]

At the adiabatic limit, the vanishing of the Laplacian term in the balance of energy equation leads to a fourth-order characteristic polynomial Eq. (34) of which one of the roots is obviously zero \((\lambda = 0)\). This root represents a neutrally stable condition in which perturbation neither grows (which requires a positive real part) or decay (which requires a negative real part) [1]. To determine whether perturbation may grow, we examine the rest of the roots corresponding to Eq. (34) and analyze the ranges of material parameters that lead to at least one root having a positive real part (and hence causes a perturbation to grow). Note that the coefficients \( b_i, i = 0, 1, 2, 3 \) in Eq. (34) are either functions of an exponentiation of the wavenumber of a particular order, that is, \( k_w^2, k_w^4 \), or independent of \( k_w \). Furthermore, these coefficients do not depend on the exponentiation of the wavenumber with multiple orders as \( a_2 \) in Eq. (19). This feature allows one to derive the cutoff wavenumber, which provides the range of wavenumbers where wave propagation is possible in the adiabatic porous media.

Now, apply the Routh–Hurwitz stability criterion to the polynomial corresponding to the non-zero roots, that is, \( b_3 \lambda^3 + b_2 \lambda^2 + b_1 \lambda + b_0 = 0 \). The necessary condition to satisfy the Routh–Hurwitz stability criterion reads

\[
b_n > 0 \text{ and } b_2 b_1 > b_3 b_0 \text{, where } n = 0, 1, 2, 3,
\]

where \( b_2 b_1 - b_3 b_0 > 0 \) can be written as

\[
\rho k M^2 \left( \rho c b + 3\alpha_m \beta T_0 \right)^2 k_w^4 > 0.
\]

This condition holds when the mobility \( k \) is positive. In analogy to the general non-isothermal case, we can identify the necessary condition that leads to instability. The loss of stability may appear if one of the following criteria is met:

1. Mobility \( k = 0 \), in which case \( b_0 \) and \( b_2 \) are both equal to 0.
2. Tangential modulus \( E_t \leq - (\beta^2 T_0 / \rho c) \) leads to \( b_0 \leq 0 \).
3. Tangential modulus $E_t \leq - (\rho c b^2 M + \beta^2 T_0 + 6 \alpha_m \beta b T_0 M) / (\rho c - 9 \alpha_m^2 T_0 M)$ leads to $b_1 \leq 0$.

4. Specific heat $c \leq 9 \alpha_m^2 T_0 M / \rho$ so that $b_3 \leq 0$.

**Remark 1**

Notice that in many THM formulations, such as Selvadurai and Suvorov [43] and Selvadurai and Suvorov [48], the work carried out or energy dissipation of the fluid and solid constituents are assumed to be negligible in the balance of energy equation. In this case, the energy balance equation, Eq. (3), may be simplified as

$$\dot{T} - \frac{\kappa}{\rho c} \frac{\partial^2 T}{\partial x^2} = 0. \quad (41)$$

Hence, the mechanical and hydraulic responses are only one-way coupled with the heat transfer process. While the temperature changes may still cause deformation and/or flow, Eq. (41) indicates that neither deformation of the solid skeleton or the pore-fluid flow may impose any influence on the temperature due to the simplified assumptions. In this special case, the characteristic equation reads,

$$
\begin{vmatrix}
-E_t k_w^2 - \rho \lambda^2 & -i(b k_w) & -i(\beta k_w) \\
0 & k_w^2 + M^{-1} \lambda & -3 \alpha_m \lambda \\
-i(b k_w) & 0 & \rho c \lambda - \kappa k_w^2
\end{vmatrix} = 0. \quad (42)
$$

In the one-way coupling THM formulations, the characteristic equation will have two roots identical with those in the fully saturated isothermal condition [29, 33, 38], while the additional root is $\lambda = -\kappa k_w^2 / (\rho c)$, which is either equal to zero (when $\kappa = 0$) or negative (when $\kappa$ is positive). In other words, if the thermal conductivity is non-zero, then the governing equations of the one-way coupling THM system and the isothermal THM system share the same necessary and sufficient conditions for stability.

### 2.3. Dispersion analysis

Even if stability is lost, numerical simulations may still continue and give meaningful results as pointed out by Abellan and de Borst [33]. However, when the THM problem becomes ill-posed, the physical length scale inferred from the physical properties vanishes, and a numerical length scale, which is often the mesh size, may influence the numerical solutions and cause mesh dependency. The dispersion analysis provides a tool to predict the vanishing of finite non-zero physical wave-length by checking whether the associated cutoff wavenumber or damping factor can be identified. Recall that a wave is considered dispersive if the phase velocity (or wave velocity, $v_p$) depends on the wavenumber [27, 29, 32, 33, 38, 49–52]. In this case, the waves of different wavelengths travel at different phase velocities, and hence, the shape of a dispersive wave may change as it propagates [53]. To capture localization of deformation properly, governing equation must be able to change the shape of an arbitrary loading wave into a stationary wave in a localization zone [18, 33]. It is well known that wave propagation in the standard single-phase continuum upon the occurrence of strain softening is not dispersive, and hence, the mesh dependency is observed [1, 33].

In this section, our objectives are to (i) investigate whether a dispersive wave can propagate at the long and short wavelength limits in the non-isothermal case, and (ii) examine the cutoff wavenumber and internal length scale when strain softening at the adiabatic limit.

#### 2.3.1. Non-isothermal case

We assume that the solution of the governing equations of a damped, harmonic wave propagating in a thermo-sensitive fully saturated two-phase porous media takes the following form:

$$\begin{bmatrix}
\frac{du}{dt} \\
\frac{dp}{dt} \\
\frac{dT}{dt}
\end{bmatrix} = \begin{bmatrix}
A_u \\
A_p \\
A_T
\end{bmatrix} e^{i(k_w x - \omega t)} = A e^{\lambda x + i(k_w x - \omega t)}, \quad (43)$$
where $A_u$, $A_p$, and $A_T$ are the amplitudes of the displacement, pore pressure, and temperature accordingly. In the dispersion analysis, we split the possible complex eigenvalue into real part ($\lambda_r$) and imaginary part ($\omega$ or $\omega_i$) as $\lambda = \lambda_r - i\omega$. According to Zhang et al. [29] and the dispersion analysis of adiabatic case later, the cutoff wavenumber can be derived using the discriminant of cubic polynomial of eigenvalue when the same order of wavenumber term exists in each coefficient of the characteristic equation (e.g., Eq. (34)). However, in the characteristic equation of non-isothermal condition (Eq. (16)), the coefficient $a_2$ has two different orders of wavenumber ($k_w^2$ and $k_w^4$), and the derivation of discriminant of quartic polynomial cannot give the explicit expression of wavenumber having the complex conjugate roots. Nevertheless, we may still determine the relation between the phase velocity and the real and imaginary parts of the eigenvalue by substituting $\lambda = \lambda_r - i\omega$ into Eq. (16). This process, based on Abellan and de Borst [33], decomposes the characteristic equation into real and imaginary parts as follows,

$$a_4\lambda_r^4 + a_3\lambda_r^3 + a_2\lambda_r^2 + a_1\lambda_r + a_0 - a_2\omega^2 - 3a_3\lambda_r\omega^2 - 6a_4\lambda_r^2\omega^2 + a_4\omega^4 + i\left(-a_1\omega - 2a_2\lambda_r\omega - 3a_3\lambda_r^2\omega - 4a_4\lambda_r^3\omega + a_3\omega^3 + 4a_4\lambda_r\omega^3\right) = 0. \quad (44)$$

The imaginary part of Eq. (44) vanishes if the following condition holds,

$$\omega = 0 \text{ or } \omega^2 = \frac{4a_4\lambda_r^3 + 3a_3\lambda_r^2 + 2a_2\lambda_r + a_1}{+4a_4\lambda_r + a_3}. \quad (45)$$

For the dispersion analysis of dynamic governing equations, we can assume $\omega \neq 0$ and take the condition of Eq. (45)2. By considering the coefficients $a_i, i = 0, 1, 2, 3, 4$ of Eqs. (17) to (21), we know that $\omega$ is expressed in terms of wavenumber ($k_w$), and the relation of phase velocity ($v_p = \omega/k_w$) and wavenumber can be derived (Appendix A). Because the phase velocity is dependent on the wavenumber, we can find out that the wave propagation is dispersive. Furthermore, by substituting Eq. (45)2 into Eq. (44), the equation of real part of eigenvalue $\lambda_r$ can be expressed as shown in the succeeding equation,

$$\left[64a_4\lambda_r^6 + 96a_3\lambda_r^5 + (48a_2\lambda_r^4 + 32a_2a_4)\lambda_r^4 + (8a_3^3 + 32a_2a_3a_4)\lambda_r^3 + (8a_2a_3^2 + 4a_2^2\lambda_r + 4a_1a_3a_4 - 16a_0a_2^2)\lambda_r^2 + (2a_2^3 + 2a_1a_3^2 - 8a_0a_3a_4)\lambda_r + a_1a_2a_3 - a_0a_2^2 - a_1a_4\right]/(16a_4^2\lambda_r^2 + 8a_4a_3\lambda_r + a_3^2) = 0. \quad (46)$$

Unfortunately, as proven by the Abel–Ruffini theorem (also referred as the Abel’s impossibility theorem [54]), there exists no general algebraic solution in radicals to polynomials of degree five or higher with arbitrary coefficients. In other words, there is no general formula that allows the real part of eigenvalue $\lambda_r$ to be expressed algebraically, even though it is still possible to solve Eq. (46) numerically. However, we can estimate $\lambda_r$ by taking long and short wavelength limits considering the coefficients $a_i, i = 0, 1, 2, 3, 4$ and Eqs. (45) to (46).

Firstly, we found that taking the long wavelength limit, that is, $k_w \rightarrow 0$, yields the eigenvalue $\lambda_r \rightarrow 0$ in Eq. (46). As demonstrated in Abellan and de Borst [33], this result leads to the relation of phase velocity and wavenumber according to Eq. (45)2. Therefore, we can explicitly derive the phase velocity for the long wavelength limit as shown below.

$$v_p = \frac{E_I\kappa + b^2kM + \rho cE_I kM + \beta^2kT_0M}{\rho(\kappa + \rho c kM)} = \sqrt{\frac{E_I}{\rho}} + \frac{b^2kM}{\rho(\kappa + \rho c kM)} + \frac{\beta^2kT_0M}{\rho(\kappa + \rho c kM)}. \quad (47)$$

Observe that the phase velocity of Eq. (47) is reduced to the classical bar velocity, $v_p = \sqrt{E_I/\rho}$, as $\kappa$ and $k$ are negligible. Figure 1 shows how the phase velocity changes depending on the thermal conductivity and permeability (or mobility $k$), where the material properties are selected from the previous studies (Sun [22], Zhang et al. [29]). When the thermal conductivity is given, for example $\kappa = 2.5 \times 10^{-3}$ kW/m°C, the phase velocity does not change until the permeability decreases below $k_{perm} \approx 1.0 \times 10^{-6}$ m/s. Besides, when the permeability is further decreased and beyond the range, $1.0 \times 10^{-8} < k_{perm} < 1.0 \times 10^{-6}$ (m/s), additional response from the phase
velocity is not observed. In other words, the phase velocity of the THM system can be influenced by how the permeability and thermal conductivity are combined, but the effect is limited.

For the short wavelength limit, that is, \( k_w \to \infty \), we can estimate that \( \lambda_r \sim k_w^{10} \) from Eq. (46) and the wave velocity become proportional to the wavenumber, \( v_p \sim k_w \), from Eq. (45). By adopting the relation of the internal length scale and damping coefficient from a single-phase rate-dependent medium [53], the internal length scale \( (l) \) is defined as follows:

\[
l = \lim_{k_w \to \infty} \left(-\frac{v_p}{\lambda_r}\right) \sim \lim_{k_w \to \infty} k_w^{-9} = 0.
\]  

This means that the internal length scale vanishes at the short wavelength limit. The loss of physical internal length scale also suggests that any grid-based numerical model that solves the THM governing equations may exhibit mesh dependency, as any regularization effect induced by multi-physical coupling may vanish if the physical length scale vanished.

In other words, the rate-dependence introduced through multiphysical coupling may not regularize the THM governing equations when softening occurs. This conclusion echoes the previous dispersion analysis of isothermal two-phase porous media by Abellan and de Borst [33], which also indicates that the internal length scale vanishes at the short wavelength limit. The wave propagation behavior of non-isothermal condition when strain softening occurs is further evaluated by numerical experiments in Section 3.2.

For the adiabatic case, we derived the internal length scale of the adiabatic THM system within a limited range of wavenumbers by expanding the derivation for isothermal porous system in Zhang et al. [29]. In addition, we conducted parametric studies to analyze how the specific heat and permeability may affect the cutoff wavenumber and the corresponding internal length scale.

2.3.2. Adiabatic Case. By assuming that the thermal conductivity is approximately zero, we obtained the characteristic equation of a damped harmonic wave propagating in a porous medium at the adiabatic limit. Based on the derivations in Section 2.2.2, we conducted a dispersion analysis and derive the expression of the internal length scale when the porous medium remains at the adiabatic limit. Our starting point is the third-order characteristic polynomial, which takes the following form,

\[
D(\lambda) = \lambda^3 + a\lambda^2 + b\lambda + c = 0,
\]  

where

\[
a = a^0 y, \quad a^0 = \frac{\rho c k M}{\rho c - 9\alpha_m^2 T_0 M},
\]
Section 2.2.2 indicates loss of stability when either one of the following conditions holds, that is, when stability of the THM system has already been lost. Recall that the stability analysis in [4] to keep the discriminant \( \Delta \) negative, we note that the quadratic polynomial of \( D(y) \) has real roots if \( \Delta \) is positive. Under the given condition in Eq. (54), we know that the coefficient \( w \) becomes negative because \( c^0 \) is negative and \( a^0 \) is positive. Besides, we can find out
that \( s \) becomes positive because \( b^0 \) is come to be positive as proved in Appendix B. Therefore, we can derive the only positive root of \( wy^2 + ry + s = 0 \) in the form of \((-r - \sqrt{r^2 - 4ws})/2w \) based on the fact that \( w < 0 \) and \( s > 0 \). In other words, this makes Eq. (56) be always negative (\( \Delta < 0 \)) when the square of the wavenumber \( y \) \((= k^2_w)\) is within the range described as follows:

\[
0 < y < \frac{-r - \sqrt{r^2 - 4ws}}{2w} \quad (= k^2_{w,cut}).
\]  

(60)

The cutoff wavenumber \((k_{w,cut})\) as a function of the permeability or mobility \((k)\), specific heat \((\rho c)\), tangential modulus \((E_t)\), reference temperature \((T_0)\), and other material properties of porous media has also been sought in this study. Because of the length of the derivation, the step-by-step derivation that leads to the expression of the cutoff wavenumber is provided in Appendix B. Meanwhile, the influences of the permeability and specific heat on the cutoff wavenumber are depicted in Figure 2. The reciprocal of permeability shows a linear relation to the cutoff wavenumber in log-log plane; however, the specific heat shows limited effect until it reaches to 1.0. In this regard, we can find out that the permeability is closely related to the cutoff wavenumber, while the specific heat has little influence on it.

Within the range of cutoff wavenumber, three roots (one real and two complex conjugate roots) of the third-order characteristic equation can be determined by Cardano’s formula. By letting \( \lambda = z - \frac{a}{2} \), the third-order polynomial Eq. (49) can be rewritten as

\[
z^3 + pz + q = 0, \quad \text{where} \quad p = \frac{1}{3}(3b - a^2), \quad q = \frac{1}{27}(2a^3 - 9ab + 27c).
\]  

(61)

This equation has three roots that take the following forms,

\[
z_1 = A + B, \quad z_{2,3} = -\frac{A + B}{2} \pm \frac{i \sqrt{3}}{2}(A - B),
\]  

(63)

where

\[
A = \sqrt[3]{-\frac{q}{2} + \sqrt{\frac{q^2}{4} + \frac{p^3}{27}}}, \quad B = \sqrt[3]{-\frac{q}{2} - \sqrt{\frac{q^2}{4} + \frac{p^3}{27}}}.
\]  

(64)

Therefore, we can rewrite the solution \( \lambda \) as follows,

\[
\lambda_1 = (A + B) - \frac{a}{3}, \quad \lambda_{2,3} = -\frac{A + B}{2} + \frac{i \sqrt{3}}{2}(A - B) - \frac{a}{3}.
\]  

(65)
and distinguish the real part and imaginary part in the roots:

$$\lambda_r = -\frac{1}{2}(A + B) - \frac{a}{3}, \quad \lambda_i = \frac{\sqrt{3}}{2}(A - B).$$  \hspace{1cm} (66)$$

By substituting the complex root into the damped harmonic equation like we did before in Eq. (43), we have (note that $\lambda_i = \omega$):

$$v(x, t) = Ae^{ik_wx}e^{\lambda_r t - i\omega t} = Ae^{ik_wx}e^{\lambda_r t - i\lambda_i t}, \quad v = [u, p, T]^T. \hspace{1cm} (67)$$

Recall the relation between the phase velocity $v_p$ and the wavenumber $k_w$,

$$v_p = \frac{|\lambda_i|}{k_w}. \hspace{1cm} (68)$$

By means of $t = x/v_p$, the damping term $e^{(\lambda_r)t}$ changes into $e^{k_w((\lambda_r)/|\lambda_i|)x} = e^{-\alpha x}$, where $\alpha$ is the damping coefficient [29]. Notice that the THM coupling introduces rate dependence to the mechanical response, even if the solid phase continuum does not exhibit any viscous behavior. As a result of this rate dependence, the internal length scale $l$ is introduced, that is,

$$l = \alpha^{-1}, \quad \alpha = \frac{\lambda_r}{|\lambda_i|} k_w, \hspace{1cm} (69)$$

in which $\lambda_r$ and $\lambda_i$ are obtained from Eq. (66). It is obvious that the definition of internal length scale holds only for dynamic analysis. The damping coefficient $\alpha$ and the internal length scale $l$ can be expressed as shown in the succeeding equation:

$$\alpha = \frac{|A + B + \frac{2}{3}a| k_w}{\sqrt{3}(A - B)}, \quad l = \frac{\sqrt{3}(A - B)}{|A + B + \frac{2}{3}a| k_w}. \hspace{1cm} (70)$$

Therefore, we can identify the internal length scale as a function of the mobility ($k$), specific heat ($pc$), wavenumber ($k_w$), reference temperature ($T_0$), tangential modulus under strain softening ($E_t$), and other material properties as follows:

$$l = f(k, pc, k_w, E_t, M, \beta, \alpha_m, T_0). \hspace{1cm} (71)$$

For brevity, the expression of the internal length scale is described in details in the Appendix C.

**Remark 2**

In the adiabatic condition, we derived the cutoff wavenumber, which guarantees the wave propagation is possible. Within this range, we can analyze how the damping coefficient changes along the wavenumber by normalizing it with the cutoff wavenumber in Figure 3.

![Figure 3. Damping coefficient ($\alpha$) versus normalized wavenumber.](image-url)
WAVE PROPAGATION IN A NON-ISOTHERMAL FLUID-SATURATED POROUS MEDIUM

Figure 4. Relationship of the internal length scale with the permeability and specific heat under the adiabatic condition.

In this figure, we can see that the damping coefficient ($\alpha$) approaches zero when the wavenumber decreases, which is a natural phenomenon considering the definition of $\alpha$. On the other hand, the damping coefficient approaches infinity when the wavenumber converges to the cutoff value, which states that the internal length scale, a reciprocal of $\alpha$, vanishes. This fact is also analogous to the case of long wavelength limit under the non-isothermal condition, Eq. (48). The effect of permeability (or mobility, $k$) and specific heat ($pc$) of porous media on the internal length scale is compared in Figure 4. We can see that the permeability has a proportional relation to the internal length scale while the specific heat has limited effect.

3. NUMERICAL EXPERIMENTS

To illustrate the influences of THM coupling on the width of localization zone, we use an implicit dynamic finite element code to simulate one-dimensional wave propagation in a thermo-sensitive fully saturated porous bar with different sets of material parameters. Our objective here is to use the numerical experiments to (i) verify the theoretical analysis on the phase velocity and internal length scales in Section 2.2 and (ii) confirm whether mesh dependency occurs when the physical internal length scale is predicted to be vanished according to Eqs. (48) and (71).

As mentioned previously in Section 2.3.1, we did not obtain the expression of internal length scale for the non-isothermal condition, as the general algebraic expression of the internal length scale does not exist according to the Abel–Ruffini theorem [54]. As a result, we first limit our focus on the adiabatic condition and performed numerical experiments to validate the analytical expression of the internal length scale. We then analyze the simulated wave propagation behavior of the non-isothermal condition with a series of numerical simulations under the different thermal conductivities. The changes of wave propagation behaviors observed in the numerical simulations due to changes of the thermal conductivity are also compared. We found that the observed behavior is consistent with the phase velocity expressed in Eq. (47).

Figure 5. One dimensional soil bar in axial compression
The numerical model consists of a softening bar constrained to move in only one direction. In addition, heat transfer and pore-fluid diffusion are also confined to be one-dimensional. The length of the bar is 10 m. At \( x = 0 \) m, the bar is fixed and has zero displacement, while a perturbation of force is applied at \( x = 10 \) m. Both pore pressure and temperature are prescribed as zero at \( x = 10 \) m. A constant time step \( \Delta t = 1.0 \times 10^{-2} \) s is used to all the numerical simulations. The absolute mass densities of soil and fluid are selected as \( \rho_s = 2,700 \) kg/m\(^3\) and \( \rho_f = 1,000 \) kg/m\(^3\). The elastic and tangential moduli under strain softening are assumed to be 30 and \(-20\) MPa, respectively, and the Biot’s modulus \((M)\) is considered to be 200 MPa. The reference temperature \( T_0 \) is set to be 20 °C, and the numerical condition of applied stress and local stress-strain diagram are depicted with boundary conditions in Figures 5 and 6. Here, \( t_0 \) is set to be 0.1 s, \( q_{t_0} \) is applied as 500 kPa, and \( \sigma_y \) values are indicated in the figures for each simulation.

### 3.1. Adiabatic case

The reference case of internal length scale under the adiabatic condition is calculated with the permeability \((k_{perm})\) of \( \frac{5.0}{10^{-3}} \) m/s and the specific heat \((pc)\) of 4.5 kJ/m\(^3\)/°C. The internal length of each case is described in the following Table II when the wavenumber is assumed to be unity. The numerical simulations are investigated with the element size of 0.4 m.

The reference case gives the internal length scale of 4.10 m, and the plastic wave is able to propagate. We can verify this from the numerical simulation results depicted in Figure 7. Nevertheless, in another two numerical experiments, one with increased permeability and the other

Figure 7. Development of the localization zone under possible wave propagation – the plastic strain moves towards the depth along the time (the reference condition, permeability = \( 5.0 \times 10^{-3} \) m/s, \( pc = 4.5 \) kJ/m\(^3\)/°C, \( \sigma_y = 30 \) MPa)
Wave propagation in a non-isothermal fluid-saturated porous medium

With lowered specific heat, the harmonic wave ceases to propagate and the plastic zone seizes at a certain depth as shown in Figure 8. This fixed plastic zone with time indicates that the wave is unable to propagate. This observation is consistent with Eq. (70), and the relationship among the internal length scale, permeability, and specific heat showcased in Figure 4. Similar plastic strain patterns were noticed by Zhang et al. [29] in dynamic wave propagation simulations under the isothermal condition.

3.2. Non-isothermal case

With the results shown in Figure 7 as the reference, we vary the thermal conductivity and determine how the thermal conductivity affects wave propagation. We assumed that the thermal conductivities of fluid and solid are the same and selected the value from the previous study by Sun [22], $\kappa = 2.5 \times 10^{-3}$ kW/m$^2$ C. According to our previous analysis, both thermal conductivity and permeability can influence on the behavior of the THM system (Figure 1). In order to analyze this effect, we conducted parametric study of thermal conductivity under two permeability conditions: (i) $5.0 \times 10^{-3}$ m/s from the reference case in Section 3.1 and (ii) $1.0 \times 10^{-10}$ m/s as low permeability case. A series of numerical simulations are performed by varying the thermal conductivities provided that the specific heat ($c_p$) is assumed to be 4.5 kW/m$^2$ C.

Firstly, we introduced the thermal conductivity into the reference case and conducted the numerical simulation. When $\kappa = 2.5 \times 10^{-3}$ kW/m$^2$ C was adopted, the numerical simulation showed little change in the plastic strain compared with the adiabatic condition in Figure 7. However, when the thermal conductivity is increased to 1.0 kW/m$^2$ C, we found the wave propagation behavior started to change. These results are depicted in Figure 9. The plastic strain is increased compared with the adiabatic case, and the plastic wave is still able to propagate along time. Considering the

Figure 8. Development of the localization zone under no wave propagation – the plastic strain stays at the same depth along the time

Figure 9. Development of the localization zone (non-isothermal condition with $\kappa = 1.0$ kW/m$^2$ C, $\sigma_y = 30$ MPa).
initial and boundary conditions of temperature field, we expect that the prescribed zero temperature at the surface (10 m) contributes additional compression to the one-dimensional bar.

Next, we started from the numerical setup of adiabatic limit with the permeability equal to $1.0 \times 10^{-10}$ m/s. When the thermal conductivity of $2.5 \times 10^{-3}$ kW/m°C was applied, the response of plastic strain gave little effects compared with the adiabatic condition. When $k$ became larger than $1.0 \times 10^{-1}$ kW/m°C, however, we found the changes of plastic localization zone. Figure 10 depicts the changes of wave propagation with different thermal conductivities under the low permeability condition. We can identify that both permeability and thermal conductivity influence on the behavior of wave propagation under strain softening from Figures 9 and 10.

Furthermore, we took two cases in Section 3.1, in which the wave was not able to propagate, and re-analyzed the simulations by introducing the thermal conductivity. Again, the thermal conductivity of $2.5 \times 10^{-3}$ kW/m°C showed little effect on both cases. Figure 11 shows when $k = 1.0$ kW/m°C was applied. We can see the width of localization zones, and the plastic strains are increased compared with adiabatic case in Figure 8. However, the plastic wave does not propagate along time. This indicates that the thermal conductivity appears limited effect on regularization.

Remark 3
We conducted additional numerical simulations for the non-isothermal case to analyze the influence of mesh size on shear band width. The permeability of $1.0 \times 10^{-10}$ m/s was selected to have enough internal length scale for stability. The thermal conductivity ($k = 2.5 \times 10^{-3}$ kW/m°C) and the specific heat ($c = 4.5$ kJ/m³°C) were adopted from the previous study by Sun [22]. The one-dimensional domain was discretized by 10, 20, 25, 30 linear finite element of equal sizes to

![Figure 10](image1.png)

![Figure 11](image2.png)
Wave propagation in a non-isothermal fluid-saturated porous medium

Figure 12. Independence of the strain localization zone width under different mesh sizes and limited changes of temperature field along the bar under various thermal conductivities (at $t = 1.0 \text{s}$ with $k_{\text{perm}} = 1.0 \times 10^{-10} \text{m/s}$, $\rho c = 4.5 \text{kJ/m}^3/\text{°C}$).

Study mesh dependency. As shown in Figure 12(a), the plastic strain distribution from the numerical simulations suggests mesh independence. In addition, Figure 12(b) describes temperature field distribution of the numerical simulations for the non-isothermal condition. With the same material properties used in the mesh study, the domain with 25 elements is selected. We can see how the temperature changes with different thermal conductivities.

4. CONCLUSION

The one-dimensional wave propagation in a full saturated, thermo-sensitive porous medium has been analyzed. The stability analysis indicates that the governing equations of the thermo-hydro-mechanics system lead to a characteristic polynomial at least one order higher than the isothermal poromechanics counterpart. By applying the Routh–Hurwitz stability criterion to this higher-order characteristic polynomial, we determine that instability may occur if (i) strain softening occurs and/or (ii) specific heat per mass is less than a critical value proportional to Biot’s modulus and the square of the thermal expansion coefficient, and (iii) when both permeability and thermal conductivity are 0. Dispersion analysis on the THM system reveals that a dispersive wave may propagate in a fully saturated, thermo-sensitive system under certain limited conditions. Nevertheless, the internal length scale introduced by the THM coupling vanishes at the short wavelength limit. For the adiabatic limit case, we derive an explicit expression of the internal length scale as a function of permeability, specific heat, wavenumber, and other material properties. The cutoff wavenumber is also identified. Our results indicate that there is a limited range of wavenumbers that allows dispersive waves to propagate at a finite speed.

APPENDIX A: RELATION BETWEEN PHASE VELOCITY AND WAVENUMBER

In the dispersion analysis of non-isothermal two-phase porous media, we may establish the relation between the phase velocity ($v_p$) and the wavenumber ($k_w$). Our starting point is Eq. (45)_2 from Section 2.3.1, which reads

$$\omega^2 = \frac{4a_4 \lambda_r^3 + 3a_3 \lambda_r^2 + 2a_2 \lambda_r + a_1}{4a_4 \lambda_r + a_3}, \quad (A.1)$$

where the coefficients are from Eqs. (17) to (20), that is,

$$a_4 = \rho (\rho c - 9\sigma_m T_0 M), \quad (A.2)$$

$$a_3 = \rho (\kappa + \rho c k M) k_w^2, \quad (A.3)$$
\[
a_2 = \left( \rho c E_t + \rho c b^2 M + \rho k M k_w^2 + \beta^2 T_0 + 6\alpha_m \beta b T_0 M - 9E_t \alpha_m^2 T_0 M \right) k_w^2, \quad (A.4)
\]

\[
a_1 = \left( E_t k + b^2 \kappa M + \rho c E_t k M + \beta^2 k T_0 M \right) k_w^4. \quad (A.5)
\]

By substituting Eqs. (A.2) to (A.5) into Eq. (A.1), we may express \( \omega \) in terms of wavenumber \( (k_w) \) as shown in the succeeding equation,

\[
\omega^2 = \frac{a_{w4} + a_{w3} k_w^2 + a_{w2} k_w^4}{a_{w1} + a_{w0} k_w^2}, \quad (A.6)
\]

where the coefficients in Eq. (A.6) are

\[
a_{w4} = 4\rho \left( \rho c - 9\alpha_m^2 T_0 M \right) \lambda_r^3, \quad (A.7)
\]

\[
a_{w3} = 3\rho(\kappa + \rho c k M) \lambda_r^2 + 2 \left( \rho c E_t + \rho c b^2 M + \beta^2 T_0 + 6\alpha_m \beta b T_0 M - 9E_t \alpha_m^2 T_0 M \right) \lambda_r \quad (A.8)
\]

\[
a_{w2} = 2(\rho c k M) \lambda_r + E_t k + b^2 \kappa M + \rho c E_t k M + \beta^2 k T_0 M, \quad (A.9)
\]

\[
a_{w1} = 4\rho \left( \rho c - 9\alpha_m^2 T_0 M \right) \lambda_r, \quad (A.10)
\]

\[
a_{w0} = \rho(\kappa + \rho c k M). \quad (A.11)
\]

Therefore, the phase velocity \( (v_p = \omega / k_w) \) can be expressed as a function of the wavenumber \( (k_w) \) and material parameters as shown in the succeeding equation,

\[
v_p = \frac{\omega}{k_w} = \sqrt{\frac{a_{w4}/k_w^2 + a_{w3} + a_{w2} k_w^2}{a_{w1}/k_w^2 + a_{w0}}}. \quad (A.12)
\]

This relation proves that the wave propagating in the porous media that has already lost stability is dispersive.

**APPENDIX B: CUTOFF WAVENUMBER FOR THE ADIABATIC CASE**

The objective of this section is to determine the cutoff wavenumber of the adiabatic THM system. At the adiabatic limit, the characteristic polynomial of the THM system takes the following form (the same with Eq. (49) to Eq. (53)),

\[
\lambda^3 + a \lambda^2 + b \lambda + c = 0, \quad (B.1)
\]

where the coefficients of the characteristic Eq. (B.1) reads

\[
a = a^0 y, \quad a^0 = \frac{\rho c k M}{\rho c - 9\alpha_m^2 T_0 M}, \quad (B.2)
\]

\[
b = b^0 y, \quad b^0 = \frac{\rho c E_t + \rho c b^2 M + \beta^2 T_0 + 6\alpha_m \beta b T_0 M - 9E_t \alpha_m^2 E_t T_0 M}{\rho(\rho c - 9\alpha_m^2 T_0 M)}, \quad (B.3)
\]

\[
c = c^0 y^2, \quad c^0 = \frac{(\rho c E_t + \beta^2 T_0) k M}{\rho(\rho c - 9\alpha_m^2 T_0 M)}, \quad (B.4)
\]

\[
y = k_w^2, \quad (B.5)
\]

The discriminant of the previous equations is denoted as

\[
\Delta = -4b^0 y^3 + a^0 b^0 y^4 + 18a^0 b^0 c^0 y^4 - 27c^0 y^4 - 4a^0 c^0 y^5, \quad (B.6)
\]
which can be rewritten in terms of the coefficients, $w$, $r$, and $s$, that is,

$$\Delta = -y^3(wy^2 + ry + s), \quad (B.7)$$

where

$$w = 4a^0c^0, \quad (B.8)$$

$$r = 27c^0 - a^2b^2 - 18d^0b^0c^0, \quad (B.9)$$

$$s = 4b^0^3. \quad (B.10)$$

Following the approach used in Section 2.3.2, we assume that stability of the adiabatic system has already lost and determine the cutoff wavenumber beyond which the dispersive wave fails to propagate at a finite speed. Assuming that the porous medium remains permeable, the condition that causes the adiabatic THM system losing stability reads

$$-b^2M < E_t < -\beta^2T_0/\rho c, \quad c > 9a_m^2T_0M/\rho, \quad k > 0. \quad (B.11)$$

Assuming that Condition (B.11) holds, we may conclude that Eq. (B.1) has one real root and two complex conjugate roots if we can prove that the discriminant in Eq. (B.6) is negative. Note that the quadratic polynomial of $wy^2 + ry + s$ in Eq. (B.7) is positive when the wave can propagate, because $y^3$, a function of wavenumber ($k$), is always positive in that case. Furthermore, by applying Condition (B.11) into Eq. (B.4) and Eq. (B.5), one may deduce that $c^0$ is strictly negative and $a^0$ is strictly positive. Therefore, we conclude that the coefficient $w$ is negative when Condition (B.11) holds. Next, we consider the term $b^0$. Assume that

$$b^0 = \frac{\rho cE_t + \rho cb^2M + \beta^2T_0 + 6a_m^2bT_0M - 9a_m^2E_tT_0M}{\rho (\rho c - 9a_m^2T_0M)} > 0. \quad (B.12)$$

This assumption implies that

$$\rho cE_t + \rho cb^2M + \beta^2T_0 + 6a_m^2bT_0M - 9a_m^2E_tT_0M > 0, \quad \because \rho c - 9a_m^2T_0M > 0 \quad (B.13)$$

$$\Rightarrow E_t > \frac{-\rho cb^2M - \beta^2T_0 - 6a_m^2bT_0M}{\rho c - 9a_m^2T_0M} \geq \frac{-\rho cb^2M - \beta^2T_0 - 6a_m^2bT_0M}{\rho c}, \quad (B.14)$$

$$\Rightarrow E_t > -b^2M - \left(\frac{\beta^2T_0 + 6a_m^2bT_0M}{\rho c}\right). \quad (B.15)$$

Given that $(\beta^2T_0 + 6a_m^2bT_0M)/\rho c \geq 0$, the assumption (B.12) is valid under Condition (B.11). Therefore, $b^0$ is positive, which in return implies that $s$ is also positive (according to Eq. (B.10)). Because $w$ and $s$ are of opposite signs, the two distinct roots of the quadratic function of $wy^2 + ry + s = 0$ always have the real parts that are of opposite signs unless the discriminant of the quadratic equation equals to 0. Furthermore, the root with a real positive part reads $(-r - \sqrt{r^2 - 4ws})/2w$. Recall that our focus is on the case where the discriminant is negative. This situation is particularly interesting, because it leads to two distinct non-real complex roots whose real parts are of opposite signs. Therefore, we can derive the range of $y$ in which the discriminant expressed in Eq. (B.6) is negative ($\Delta < 0$), that is,

$$0 < y \left(= k_w^2\right) < \frac{-r - \sqrt{r^2 - 4ws}}{2w}. \quad (B.16)$$
where
\[ w = 4a^3c^0, \] (B.17)
\[ r = 27c^0 - a^2b^2c^0 - 18a^0b^0c^0, \] (B.18)
\[ s = 4b^0. \] (B.19)

As a result, the cutoff wavenumber can be written as
\[ k_{w, \text{cut}} = \sqrt{-\frac{-r - \sqrt{r^2 - 4ws}}{2w}}, \] (B.20)
in which each coefficient \((w, r, s)\) reads
\[ w = \frac{4k^4M^4t^3}{\rho^3 (\rho c - 9\alpha_m^2M T_0)^4}. \] (B.21)
\[ r = \frac{27k^2M^2 (\rho c E_t + \beta^2 T_0)^2}{\rho^2 (\rho c - 9\alpha_m^2M T_0)^2} - \frac{18ck^2M^2 (\rho c E_t + \beta^2 T_0) (\rho c E_t + \rho cb^2M + \beta^2 T_0 + 6\alpha_m b \beta M T_0 - 9\alpha_m^2E_t M T_0)}{\rho (\rho c - 9\alpha_m^2M T_0)^3} - \frac{c^2k^2M^2 (\rho c E_t + \rho cb^2M + \beta^2 T_0 + 6\alpha_m b \beta M T_0 - 9\alpha_m^2E_t M T_0)^2}{(\rho c - 9\alpha_m^2M T_0)^4}. \] (B.22)
\[ s = \frac{4 (\rho c E_t + \rho cb^2M + \beta^2 T_0 + 6\alpha_m b \beta M T_0 - 9\alpha_m^2E_t M T_0)^3}{\rho^3 (\rho c - 9\alpha_m^2M T_0)^3}. \] (B.23)

As a result, the cutoff wavenumber can be expressed as a function of mobility \((k)\), specific heat \((\rho c)\), tangential modulus under strain softening \((E_t)\), reference temperature \((T_0)\), and other material parameters:
\[ k_{w, \text{cut}} = f (k, \rho c, E_t, T_0, b, M, \beta, \alpha_m). \] (B.24)

APPENDIX C: INTERNAL LENGTH SCALE FOR THE ADIABATIC CASE

The objective of this section is to determine the internal length scale of the adiabatic THM system. Considering the damping coefficient in Eq. (70), the coefficients in Eqs. (61) and (64) are written as follows:
\[ \alpha = \frac{|A + B + \frac{2}{3}a| k_w}{\sqrt{3}(A - B)}, \] (C.1)
where
\[ A = \sqrt[3]{\frac{q}{2} + \frac{q^2}{4} + \frac{p^3}{27}}, \quad B = \sqrt[3]{-\frac{q}{2} - \sqrt{\frac{q^2}{4} + \frac{p^3}{27}}}. \] (C.2)
with

\[ p = \frac{1}{3}(3b - a^2), \quad q = \frac{1}{27}(2a^3 - 9ab + 27c). \quad (C.3) \]

Here, we can express \( p \), \( q \) in terms of material parameters:

\[
p = \left[ - \frac{k^2 M^2 \rho c \beta^2 k_w^4}{3(\rho c - 9\alpha_m^2 M^2 T_0)^2} + \frac{(\rho c E_t + \rho cb^2 M + \beta^2 T_0 + 6\alpha_m \beta b M T_0 - 9\alpha_m^2 E_t M T_0) k_w^2}{\rho (\rho c - 9\alpha_m^2 M^2 T_0)} \right],
\]

\[
q = \left[ \frac{2\rho^3 c^3 k^3 M^3 k_w^6}{27(\rho c - 9\alpha_m^2 M^2 T_0)^3} \right] + \frac{k M (\rho c E_t + \beta^2 T_0) k_w^4}{\rho (\rho c - 9\alpha_m^2 M^2 T_0)} - \frac{c k M (\rho c E_t + \rho cb^2 M + \beta^2 T_0 + 6\alpha_m \beta b M T_0 - 9\alpha_m^2 E_t M T_0) k_w^4}{3(\rho c - 9\alpha_m^2 M^2 T_0)^2}. \quad (C.4) \]

By rearranging the expression with respect to the permeability \( k \), we can express the values of \(-\frac{q}{2}\) and \(q^2/4 + p^3/25\) in Eq. (C.2) as follows:

\[
-\frac{q}{2} = a_{11} k + a_{12} k^3, \quad (C.6) \]

\[
\frac{q^2}{4} + \frac{p^3}{27} = a_{21} + a_{22} k^2 + a_{23} k^4, \quad (C.7) \]

where

\[
a_{11} = \left[ - \frac{\rho c E_t + \beta^2 T_0}{2\rho (\rho c - 9\alpha_m^2 M^2 T_0)} + \frac{c (\rho c E_t + \rho cb^2 M + \beta^2 T_0 + 6\alpha_m \beta b M T_0 - 9\alpha_m^2 E_t M T_0)}{6(\rho c - 9\alpha_m^2 M^2 T_0)^2} \right] M k_w^4, \quad (C.8) \]

\[
a_{12} = \left[ - \frac{\rho^3 c^3}{27(\rho c - 9\alpha_m^2 M^2 T_0)^3} \right] M^3 k_w^6, \quad (C.9) \]

\[
a_{21} = \left[ \frac{(\rho c E_t + \rho cb^2 M + \beta^2 T_0 + 6\alpha_m \beta b M T_0 - 9\alpha_m^2 E_t M T_0)^3}{27\rho^3 (\rho c - 9\alpha_m^2 M^2 T_0)^3} \right] k_w^6, \quad (C.10) \]

\[
a_{22} = \left[ \frac{(\rho c E_t + \beta^2 T_0)^2}{4\rho^2 (\rho c - 9\alpha_m^2 M^2 T_0)^2} - \frac{c (\rho c E_t + \beta^2 T_0)(\rho c E_t + \rho cb^2 M + \beta^2 T_0 + 6\alpha_m \beta b M T_0 - 9\alpha_m^2 E_t M T_0)}{6\rho (\rho c - 9\alpha_m^2 M^2 T_0)^3} \right] M^2 k_w^8 - \frac{c^2 (\rho c E_t + \rho cb^2 M + \beta^2 T_0 + 6\alpha_m \beta b M T_0 - 9\alpha_m^2 E_t M T_0)^2}{108 (\rho c - 9\alpha_m^2 M^2 T_0)^4}, \quad (C.11) \]

\[
a_{23} = \left[ \frac{\rho^2 c^3 (\rho c E_t + \beta^2 T_0)}{27 (\rho c - 9\alpha_m^2 M^2 T_0)^4} \right] M^4 k_w^{10}. \quad (C.12) \]

The damping coefficient \( \alpha \) in Eq. (70) can be expressed as
By adopting the small permeability as in the previous study [29], the limit form of Eq. (C.14) with respect to a small value of $k$ is

$$a = k_w \frac{A + B + \frac{2}{3}a}{\sqrt[3]{(A - B)}} \quad \text{with} \quad a = a_0 k \quad \text{and} \quad a_0 = \left[ \frac{\rho c M}{\rho c - 9\alpha_m^2 T_0 M} \right] k_w^2, \quad (C.13)$$

or equivalently as

$$\alpha = \frac{k_w \left[ \sqrt[3]{a_11 + a_12k^3 + \sqrt[3]{a_21} + a_22k^2 + a_23k^4 + \frac{3}{2}a_1k_0k_w^2} \right]}{\sqrt[3]{\left( \sqrt[3]{a_11 + a_12k^3 + \sqrt[3]{a_21} + a_22k^2 + a_23k^4 - \sqrt[3]{a_11 + a_12k^3 - \sqrt[3]{a_21} + a_22k^2 + a_23k^4} \right)}}. \quad (C.14)$$

By adopting the small permeability as in the previous study [29], the limit form of Eq. (C.14) with respect to a small value of $k$ is

$$\alpha \approx \frac{k_w \left[ \sqrt[3]{a_11 + \sqrt[3]{a_21} + \sqrt[3]{a_11 - \sqrt[3]{a_21} + \frac{2}{3}a_0k_0k_w^2} \right]}{\sqrt[3]{\left( \sqrt[3]{a_11 + \sqrt[3]{a_21}} - \sqrt[3]{a_11 - \sqrt[3]{a_21}} \right)}}. \quad (C.15)$$

Therefore, the internal length scale ($l$), which is a reciprocal of the damping coefficient, can be calculated as a function of the mobility ($k$), specific heat ($\rho c$), wavenumber ($k_w$), tangential modulus under strain softening ($E_t$), reference temperature ($T_0$), and other material properties as follows:

$$l = f(k, \rho c, k_w, E_t, M, \beta, \alpha_m, T_0) = \alpha^{-1} \approx \frac{\sqrt[3]{\left( \sqrt[3]{a_11 + \sqrt[3]{a_21}} - \sqrt[3]{a_11 - \sqrt[3]{a_21}} \right)}}{k_w \left[ \sqrt[3]{a_11 + \sqrt[3]{a_21} + \sqrt[3]{a_11 - \sqrt[3]{a_21} + \frac{2}{3}a_0k_0k_w^2} \right]}}. \quad (C.16)$$
